

Session 13: Analyzing Text Data in Pandas

Q1: Create the following columns in the DataFrame “courses”:

- first_name: the first name of the instructor. Use NaN if not available.
- last_name: the last name of the instructor. Use Nan if not available.

```
[10]: courses['first_name']=courses['instructor'].apply(getFirst)

[11]: def getLast(s):
        if type(s)!=str:
            return nan
        l=s.split(',')
        if len(l)<=1:
            return nan
        return l[0].strip()
        courses['last_name']=courses['instructor'].apply(getLast)

[12]: # Alternative method using one function for both
        def getName(s,kind):
            if type(s)!=str:
                return nan
            l=s.split(',')
            if len(l)<=1:
                return nan
            if kind=='first':
                return l[1].strip()
            else:
                return l[0].strip()
        courses['first_name']=courses['instructor'].apply(getName,kind='first')
        courses['last_name']=courses['instructor'].apply(getName,kind='last')

[13]: courses[['instructor','first_name','last_name']].head()

           instructor first_name last_name
0  Hopkins, Merle, W      Merle  Hopkins
1  Hopkins, Merle, W      Merle  Hopkins
2  Hopkins, Merle, W      Merle  Hopkins
3  Hopkins, Merle, W      Merle  Hopkins
4                NaN        NaN        NaN
```

Q2: Extract the hour from the column “end_time”, and convert it to integers using “pd.to_numeric” (with errors=‘coerce’). Then create a columns called “evening” in the DataFrame “courses”, corresponding to whether the hour is greater than or equal to 18.

```
[14]: from numpy import nan
        def getHour(s):
            if type(s)!=str:
                return nan
            l=s.split(':')
            if len(l)>=3:
                return l[0]
            else:
                return nan
        getHour('10:00:00')
```

```
'10'
```

```
[15]: getHour('TBA')
```

```
nan
```

```
[16]: hours=pd.to_numeric(courses['end_time'].apply(getHour),errors='coerce')
      hours.head()
```

```
0    11.0
```

```
1     9.0
```

```
2    11.0
```

```
3    13.0
```

```
4    11.0
```

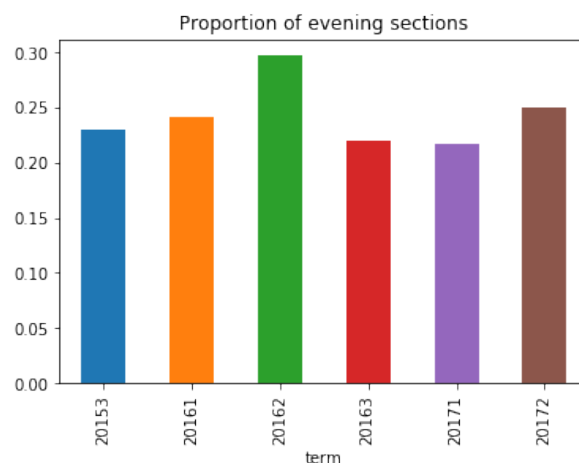

```
Name: end_time, dtype: float64
```

```
[17]: courses['evening']=(hours>=18)
```

Once you have created the column, you can compute the proportion of evening courses for each term.

```
[38]: courses.groupby('term')['evening'].mean()\
      .plot(kind='bar',title='Proportion of evening sections')
```

```
<matplotlib.axes._subplots.AxesSubplot at 0x7f1c6e3ae208>
```

Q3: Redo Q1 and Q2 using vectorized string methods already in Pandas, rather than writing your own function and calling Series.apply.

```
[30]: # Q1
```

```
courses['first_name']=courses['instructor'].str.split(',').str[1].str.strip()
courses['last_name']=courses['instructor'].str.split(',').str[0]
```

```
[31]: # Checking outputs for Q1
```

```
courses[['first_name','last_name']].head()
```

```
first_name last_name
0      Merle  Hopkins
1      Merle  Hopkins
2      Merle  Hopkins
3      Merle  Hopkins
4        NaN      NaN
```

```
[32]: courses['first_name'][0]
```

```
'Merle'
```

```
[33]: # Q2
```

```
courses['evening']=pd.to_numeric(courses['end_time'].str.split(':').str[0]\
                                ,errors='coerce')>=18
```

```
[34]: # Checking outputs for Q2
```

```
courses.groupby('term')['evening'].mean()
```

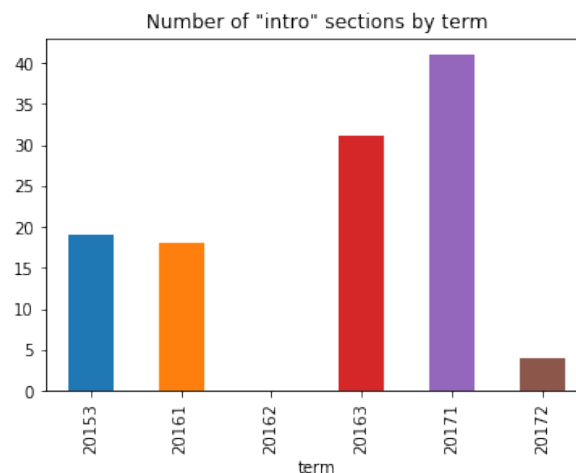

```
term
20153    0.229814
20161    0.241379
20162    0.297297
20163    0.219911
20171    0.216590
20172    0.250000
Name: evening, dtype: float64
```

Q4: Plot the number of sections by term whose title contains the string “intro” (ignoring cases).

```
[35]: import re
```

```
courses['analytics']=courses.title.str.contains('intro',flags=re.IGNORECASE)
courses.groupby('term')['analytics'].sum()\
    .plot(kind='bar',title='Number of "intro" sections by term')
```

```
<matplotlib.axes._subplots.AxesSubplot at 0x7f1c6e2e6a58>
```

(Optional) Q5: Run the following code to load in professor information, and merge it with the “courses” DataFrame using the “first_name” and “last_name” columns you have created. Then group by the “Role” and “Promotion” of professors and plot the percentage of sections taught by each group scheduled in the evening, as follows.

```
[36]: professors=pd.read_csv('Professor_information.csv',encoding='latin1')\
      [['First_Name','Last_Name','Role','Promotion']]\
      professors.head()
```

	First_Name	Last_Name	Role	Promotion
0	Arif	Ansari	Clinical	Full
1	Yehuda	Bassok	Tenure Track	Full
2	Murat	Bayiz	Clinical	Associate
3	Jacob	Bien	Tenure Track	Assistant
4	Sriram	Dasu	Tenure Track	Associate

```
[37]: courses2=courses.merge(professors,\
    left_on=['first_name','last_name'],\
    right_on=['First_Name','Last_Name'],how='left')
    courses2.groupby(['Role','Promotion'])['evening'].mean()\
    .sort_values().plot(kind='bar',title='Percentage of teachings in the evening')
```

<matplotlib.axes._subplots.AxesSubplot at 0x7f1c6e447978>
