Handout for Session 7

1. For loops and dictionaries

```
[1]: # Iterating through a dictionary
     d={'apple':5,'rice':4,'broccoli':8}
     for key in d:
         value=d[key]
         print(key, value)
apple 5
rice 4
broccoli 8
[2]: # Printing the dictionary in alphabetical order
     for key in sorted(d.keys()):
         print(key,d[key])
apple 5
broccoli 8
rice 4
[3]: # Building a dictionary iteratively
     l=['apple','rice','broccoli']
     d=\{\}
     for item in 1:
         d[item]=len(item)
{'apple': 5, 'rice': 4, 'broccoli': 8}
```

Q1: Given the following dictionaries countaining word counts (total and current), use a for loop to iterate through the dictionary current and add the counts to the dictionary total. (If the word is not found in total, you have to first initialize the value in total to zero before adding.)

2. Breaking Down Case 7a from Last Session (4 Step Method)

Step 1: Describe the task succintly and precisely

Obtain a list of unique domain names from a specified mail log, and print the list in alphabetical order.

Step 2: Decompose the task into components and describe how to do each in English

- A. Traverse through the mail log and filter for lines starting with "From:"
 - **B.** Obtain the domain name from each line.
 - C. Maintain a list of unique domain names (using Q4 from last session).
 - **D.** Sort the list and print the elements.

Step 3: Translate each component into code and test them independently

```
[6]: # A. Traverse through the mail log and filter for lines starting with "From:"...
     file=open('mbox-short.txt','r')
     for line in file:
         line=line.strip()
         if line.startswith("From:"):
             print(line)
From: stephen.marquard@uct.ac.za
From: louis@media.berkeley.edu
From: zqian@umich.edu
From: rjlowe@iupui.edu
[7]: # B. Obtain the domain name from each line
     line='From: stephen.marquard@uct.ac.za'
     domain=line.split('0')[1]
     domain
'uct.ac.za'
[8]: # C. Maintain a list of unique domain names
     l=['berkeley.edu']
     domain='uct.ac.za'
     if domain not in 1:
         1.append(domain)
     1
['berkeley.edu', 'uct.ac.za']
[9]: domain='uct.ac.za'
     if domain not in 1:
         1.append(domain)
     1
['berkeley.edu', 'uct.ac.za']
[10]: # D. Sort the list and print the elements
      l=['c','a','b']
      l=sorted(1)
      for e in 1:
          print(e)
a
b
С
```

Step 4: Combine Together and Test

i) Copy paste all the code together

```
# A. Traverse through the mail log and filter for lines starting with "From:"...
file=open('mbox-short.txt','r')
for line in file:
   line=line.strip()
    if line.startswith("From:"):
        print(line)
# B. Obtain the domain name from each line
line='From: stephen.marquard@uct.ac.za'
domain=line.split('0')[1]
# C. Maintain a list of unique domain names
l=['berkeley.edu']
domain='uct.ac.za'
if domain not in 1:
    1.append(domain)
# D. Sort the list and print the elements
l=['c','a','b']
l=sorted(1)
for e in 1:
   print(e)
```

- ii) Review the logical relationship based on the English descriptions in Step 2: Component B and C are inside the loop of component A (except that the initialization of the list should come first). Component D should take place afterward.
- iii) Combine the code appropriately and test.

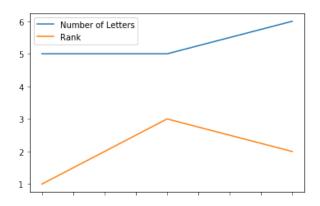

```
[11]: l=[] # C1. Initialize the list of unique elements
      # A. Traverse through the mail log and filter for lines starting with "From:"...
      file=open('mbox-short.txt','r')
      for line in file:
          line=line.strip()
          if line.startswith("From:"):
              domain=line.split('@')[1] # B. Obtain the domain name from each line
              if domain not in 1:
                                         # C2. Maintain the list of unique elements
                  1.append(domain)
      # D. Sort and print
      for e in sorted(1):
          print(e)
caret.cam.ac.uk
gmail.com
iupui.edu
media.berkeley.edu
uct.ac.za
```

Q2: Apply the above 4 step method to solve case 7b) from last session.

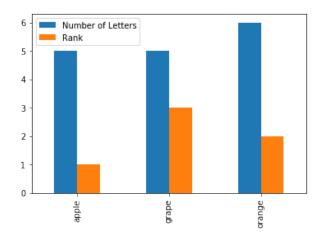

3. Pandas DataFrame Basics

```
[16]: dic1={'orange':6,'grape':5,'apple':5}
      dic2={'apple':'M','grape':'S','orange':'M'}
[17]: import pandas as pd
     df=pd.DataFrame({'Number of Letters':dic1,'Size':dic2})
       Number of Letters Size
apple
                        5
grape
                             S
                        6
                             Μ
orange
[18]: df.sort_values(by='Number of Letters',ascending=False)
        Number of Letters Size
orange
                        5
apple
                             Μ
                        5
                             S
grape
[19]: df.sort_values(by=['Number of Letters', 'Size'], ascending=[False,True])
        Number of Letters Size
orange
apple
                        5
                             Μ
                        5
                             S
grape
[38]: df
        Number of Letters Size Rank
apple
                       5 M
                        5
                          S
                                   3
grape
                                   2
                             М
orange
[37]: df['Rank']=[1,3,2]
[39]: df.head(2)
       Number of Letters Size Rank
                       5
apple
                                  1
                       5
                            S
                                  3
grape
[40]: df.tail(1)
        Number of Letters Size Rank
                        6
                            M
                                   2
orange
```

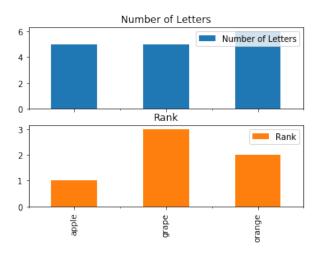

[41]: import matplotlib.pyplot as plt
 df.plot()
 plt.show()

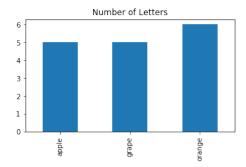

[27]: df.plot(kind='bar')
 plt.show()

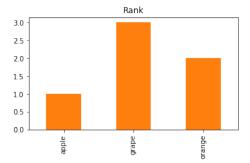

[28]: df.plot(kind='bar', subplots=True)
 plt.show()

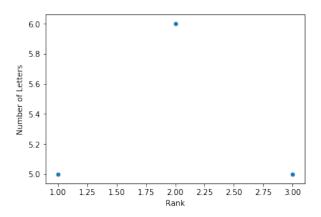

[29]: df.plot(kind='bar',subplots=True,figsize=(12,3),legend=False,layout=(1,2))
 plt.show()

[30]: df.plot(x='Rank',y='Number of Letters',kind='scatter')
 plt.show()

```
[31]: df.to_csv('session7_output.csv')
```

[32]: pd.read_csv('session7_output.csv',index_col=0)

Number of Letters Size Rank apple 5 M 1 grape 5 S S 3 orange 6 M 2

Q3-a: Create the following DataFrame and name it phones.

[33]:

price screen size
Samsung S9 619 5.8
iPhone 8 599 4.7
iPhone XR 749 6.1

Q3-b: Sort the columns in desrending order by screen size.

Q3-c: Obtain only the first two rows of the DataFrame (after sorting by screen size).

Q3-d: Create a scatter plot where x axis is screen size and y axis is price.
